1 **I. Introduction**

2 **A. Identification of Witness**

3 **Q Please state your name, employer and business address.**

4 A My name is Salvatore D. Marano, P.E. I am employed by Jacobs Consultancy,  
5 Inc. ("Jacobs Consultancy"). My business address is 5995 Rogerdale Road,  
6 Houston, TX 77072.

7

8 **Q What position do you hold at Jacobs Consultancy?**

9 A I am currently the Managing Director of Jacobs Consultancy's Utilities Practice.

10

11 **Q Please describe the activities of Jacobs Consultancy.**

12 A Jacobs Engineering Group is one of the largest professional service  
13 organizations in the world with over 55,000 employees worldwide. Jacobs  
14 Consultancy is part of the Jacobs Engineering Group. Jacobs Consultancy's  
15 Utilities Practice serves both the public and private sectors, providing  
16 management, engineering and operations related advisory services to clients  
17 globally. Engagements in the gas and electric utility industries include litigation  
18 support, asset integrity, merger and acquisition assistance, management audits,  
19 budget reviews, and policy and procedure reviews.

20

21 **B. Purpose of Testimony**

22 **Q Please describe the purpose of your testimony in this proceeding.**

23 A The purpose of my testimony is to provide evidence and analysis in support of  
24 The Peoples Gas Light and Coke Company's ("PGL") requested Infrastructure  
25 Cost Recovery Rider ("Rider ICR"), which, if granted, PGL will use to implement  
26 its Accelerated Infrastructure Replacement Program.

27

28 PGL seeks to accelerate the replacement of its gas mains and services  
29 infrastructure and achieve modernization of its aging cast iron ("CI") and ductile  
30 iron ("DI") (together "CI/DI") as well as its antiquated low-pressure system.

31

32 Saddled with this antiquated system, some of which is over one hundred years  
33 old, and the risk posed by a cast and ductile iron main system, PGL has  
34 prudently managed this system and the risks it poses. PGL's performance in this  
35 area is well in line with acceptable industry measures. However, there is a need  
36 to pursue a more accelerated approach of upgrading this system to prevent or  
37 mitigate foreseeable future risk of system and asset failure.

38

39 In its Order for PGL's most recent rate case (Docket No. 07-0242), the Illinois  
40 Commerce Commission ("Commission") stated that in order to approve PGL's  
41 requested rate recovery mechanism for an accelerated replacement program,  
42 PGL needed to establish a record providing specific types of information  
43 supporting its request. Specifically, the Commission stated that it required the  
44 following information to consider granting PGL's Rider ICR:

- 45 • A detailed description and cost analysis of the proposed system  
46 modernization;
- 47 • An identification and evaluation of the range of technology options considered  
48 and analysis and justification of the proposed technology approach;
- 49 • A detailed identification and description of the functionalities of the new  
50 system, related both to system operation as well as on the customer side of  
51 the meter, as well as an identification and justification of functionalities  
52 foregone;
- 53 • Analysis of the benefits of the system modernization, both to system  
54 operation as well as to customers, including reductions in system costs as  
55 well as an analysis of the range and benefits of potential new products and  
56 services for customers made possible by the system modernization;
- 57 • An analysis of regulatory mechanisms to allow companies to both recover  
58 their costs of system modernization as well as to flow reduced system costs  
59 back to customers; and
- 60 • An identification and analysis of legal or regulatory barriers to the  
61 implementation of system modernization.

62 (07-0241/07-0242 Cons. Order at 162.)

63  
64 My testimony will provide my opinion and support for the accelerated  
65 replacement of PGL's gas mains and services infrastructure, based on the need  
66 for reduction of future risk to the public, the public good created by a modern  
67 asset-based gas distribution system and the economic advantages of an  
68 accelerated program. This testimony will address the first four items of

69 information requested above by the ICC. The last two items of information  
70 requested by the Commission are addressed by the testimony of James Schott  
71 and Valerie Grace.

72

73 **Q Can you summarize the approach that Jacobs Consultancy utilized in**  
74 **carrying out this work?**

75 **A** The approach to conducting this independent review and analysis included:

- 76 • Identification and review of relevant documents from previous rate cases for  
77 both PGL and other operating companies;
- 78 • Identification and review of PGL records and filings;
- 79 • Conducting discussions with the appropriate subject matter experts from  
80 PGL, who have responsibility for gas operations, engineering, and  
81 accounting;
- 82 • Examination of PGL gas operations and engineering policies, procedures and  
83 practices regarding the conversion of the low-pressure portion of the system  
84 to medium-pressure, and the replacement of higher-risk pipe materials (e.g.,  
85 cast iron, ductile iron, bare steel, polyvinylchloride (PVC) plastic pipe);
- 86 • Review of gas operations and engineering policy, procedures and practices  
87 regarding the Main Ranking Index program;
- 88 • Application of my knowledge of and experience with the industry generally  
89 and, in particular, with specific comparable utilities; and
- 90 • Field visits and assessments of operating conditions for the implementation of  
91 PGL's pipe replacement policies.

92

93 **Q Who performed this work?**

94 A This independent review was performed by me and, under my direct supervision;  
95 Jacobs Consultancy staff member Christopher Pioli supported the review of  
96 documents and the development of the cost benefit model. Copies of our  
97 resumes are included in EXHIBIT SDM-1.23.

98

99 **C. Summary of Conclusions**

100 **Q Please summarize your specific conclusions, based on the findings of your**  
101 **detailed review and analysis.**

102 A PGL operates a gas distribution system, which serves residences and  
103 businesses located in the City of Chicago. These customers are served through  
104 a network of low and medium-pressure pipe. This system is comprised of 4,029  
105 miles of main is comprised of 1,629 miles of cast iron and 300 miles of ductile  
106 iron, the balance being steel or polyethylene pipe. Over 50% of these gas  
107 distribution mains were installed prior to the November 12, 1970 effective date of  
108 Title 49 Part 192 of the Code of Federal Regulations "Transportation of Natural  
109 and Other Gas by Pipelines: Minimum Federal Safety Standards." Indeed, some  
110 existing pipe was installed as early as the 1860s.

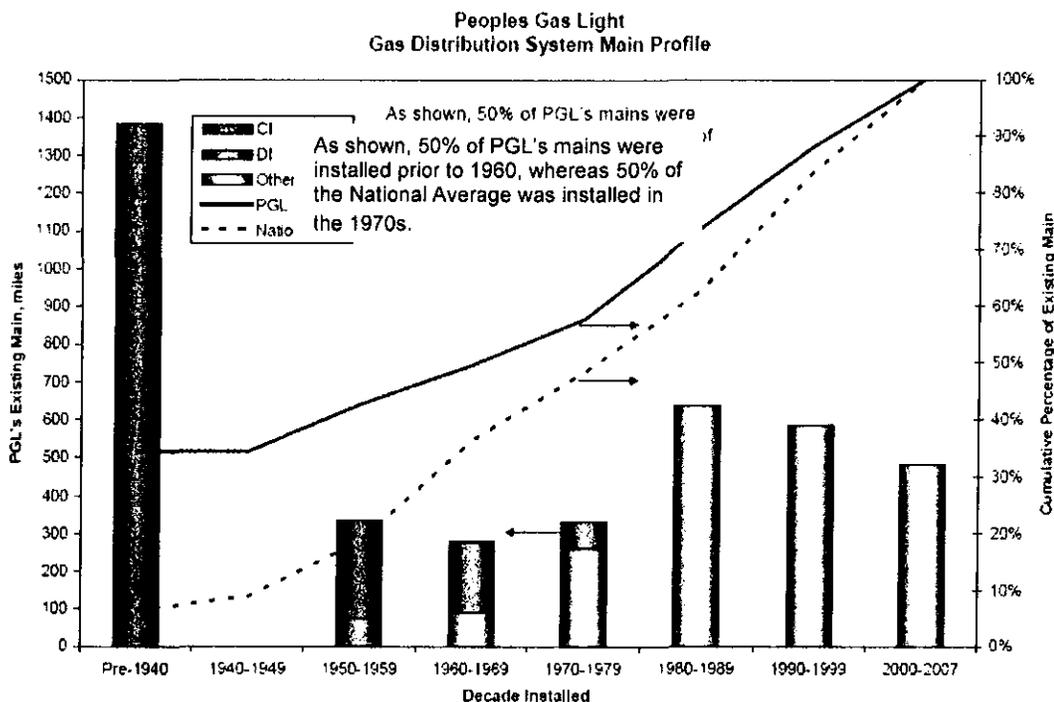

111

112 Cast and ductile iron pipe are higher-risk materials because of their unpredictable  
113 and catastrophic failure mode. The potential consequences of cast or ductile iron  
114 pipe failure increases with operating pressure. PGL has the largest percentage of  
115 cast and ductile iron pipe in its gas distribution system (47.9%) when compared

116 to any other gas distribution system operator serving the five largest U.S.  
117 metropolitan areas. Of the eleven largest cast and ductile iron gas distribution  
118 systems, PGL has the second largest percentage of cast and ductile iron pipe. In  
119 the U.S., PGL has the fifth largest cast iron and the largest ductile iron content.  
120 PGL has about 16% of its cast and ductile iron pipe operating at medium-  
121 pressure; this is more than Public Service Electric and Gas in New Jersey, which  
122 has the largest cast and ductile iron system in the U.S. Finally, the average age  
123 of PGL's system is about 15 to 20 years older than the national average.

124  
125 Accelerating the replacement of these higher-risk materials will increase system  
126 safety and reduce the likelihood of subjecting the public and customers to the  
127 adverse effects of pipe failures.

**Exhibit SDM – 1.1 – Gas Distribution System Main Profile**

129

130

131

132

133

134

135

136

137

138

139

No beneficial functionalities of a low-pressure system will be foregone by eliminating the low-pressure system. The low-pressure system is a legacy system from the days when customers received manufactured gas. No new low-pressure systems are installed today. Modernizing the gas distribution system by the elimination of the low-pressure system and replacement of higher-risk cast and ductile iron main will improve system safety (e.g., expand the use of excess-flow valves, a technology that can prevent incidents caused by damage to service lines) and reliability (e.g., eliminate gas outages caused by water infiltration of low-pressure mains).

140 In addition to increasing safety and reliability, PGL's system modernization, will  
141 provide many other benefits. The customers will benefit from having a greater  
142 selection of gas appliances to choose from, including more efficient and  
143 environmentally-friendly models, a reduction in PGL's inside safety inspections  
144 and the customer inconvenience they cause, reduced gas costs associated with  
145 lost gas and more accurate gas volume metering. Operationally, PGL will benefit  
146 from the elimination of an entire class of gas pressure regulator stations, a  
147 potential reduction in third party excavation damage, an ability to isolate smaller  
148 portions of the system, a reduction in leak repairs and increased safety for  
149 maintenance crews.

150  
151 The accelerated replacement program also has environmental benefits.  
152 Replacing cast and ductile iron pipe will reduce the amount of lost gas, thereby  
153 lowering greenhouse gas emissions. Upgrading the low-pressure system to a  
154 medium-pressure system will eliminate water infiltration and the need to dispose  
155 of water collected from the low-pressure system as a hazardous material.  
156 Furthermore, if the City of Chicago approved the use of coring and vacuum  
157 excavation technology and the re-use of soil, the amount of soil that must be  
158 hauled away and disposed of in landfills would be further reduced.

159  
160 The replacement of mains and associated service lines made from higher-risk  
161 materials and the relocation of inside meter sets to the outside will provide the  
162 benefits stated above to the general public, the customers located in the City of

163 Chicago and the workers that maintain the vast utility infrastructure. Additionally,  
164 our cost analysis shows that the cost of modernizing the legacy gas pipe system  
165 can be reduced if the current replacement program is accelerated. The  
166 accelerated replacement program will continue to replace mains due to of  
167 unacceptable risk (condition replacement) and public works projects (enforced  
168 replacement). The proposed zonal replacement approach will eliminate higher-  
169 risk pipe, while reducing the inconvenience to the public. As stated in my  
170 testimony, accelerated programs such as the one proposed by PGL are in  
171 progress in numerous states domestically, which are supported by the state  
172 regulatory agencies for several types of high risk materials. Internationally, in the  
173 United Kingdom ("UK"), the regulator has supported the accelerated programs for  
174 systems containing very large amounts of cast iron and ductile iron.

175  
176 In summary, my testimony supports the fact that PGL prudently operates one of  
177 the oldest gas distribution systems that contains some of the largest portions of  
178 high risk materials -- both cast iron and ductile iron -- in the country. However,  
179 because of the unpredictable and catastrophic failure modes of these materials,  
180 the total benefits identified that will accrue to all stakeholders by accelerating the  
181 upgrade and modernization of PGL's system support the proposed request by  
182 PGL.

183

184           **D.    Attachments to Testimony**

185           Below is an index itemizing the Exhibits to my testimony.  While images of

186           certain of these Exhibits are embedded in my testimony, copies of each also are

187           attached separately.

188

189

**E. Background and Experience**

190

**Q Please summarize your professional background and your experience in the utility industry.**

191

192

**A** I hold a Bachelor of Science degree in Mechanical Engineering from Fairleigh Dickinson University and Master of Science from New Jersey Institute of Technology. I am a registered Professional Engineer in the State of New Jersey.

193

194

195

I began my career in the Gas Engineering Department at Consolidated Edison Company of New York ("Con Edison"). I then moved to Elizabethtown Gas Company ("Elizabethtown Gas") in New Jersey where I spent 16 years in various operating and engineering positions. I then became a Vice President of the parent company of Elizabethtown Gas, NUI Corporation. I have spent the past 12

199

200

years in consulting positions, 5 years at Stone & Webster Consultants as the Vice President of the Gas Consulting Group and the past 7 years as Director and now

201

202

Managing Director of Jacobs Consultancy's Utilities Practice. During these consulting assignments, I have led engagements both domestically and

203

204

internationally, performing merger and acquisition due diligence assessments for gas and electric utilities for both potential buyers and government agencies. I

205

206

have led assignments in the area of cast iron, ductile iron, steel and plastic replacement programs and risk model assessments, and I have advised on

207

208 policy decisions relating to the management of those materials. I have also  
209 managed numerous assignments related to operations and safety improvements  
210 for gas and electric utilities.

211 **Q In particular, what is your direct experience relating to operating and**  
212 **maintaining cast iron and ductile iron systems?**

213 **A** During my career I have been intimately involved with the direct management of  
214 gas systems at both Con Edison and Elizabethtown Gas that operated in very  
215 dense urban areas and contained large amounts of cast iron and ductile iron  
216 materials.

217  
218 Internationally, I have performed numerous assignments for Transco (now  
219 National Grid UK), which was the largest operator of cast iron and ductile iron  
220 mains in the world. These assignments included: a review of their risk models for  
221 both cast iron and ductile iron; a critique of the proposed 30 year replacement  
222 program for all the materials that the UK regulator requested they undertake; and  
223 involvement in litigation cases involving explosion of cast iron and ductile iron  
224 pipe. The litigation involving the replacement of the ductile iron pipe focused on  
225 an explosion and demolition of a home in Larkhall Scotland, killing a family of 4.  
226 The charges brought against the company were Culpable Corporate Homicide  
227 and violation of the UK's Health and Safety Act 1974.

228  
229 I performed a review of the cast iron gas distribution system for a potential buyer  
230 of CEGI in Rio de Janeiro. I conducted a review of the cast iron zone

231 replacement program for the State of Victoria in Australia prior to its privatizing of  
232 the networks.

233  
234 Other domestic experience includes due diligence reviews of the management  
235 and operation of the cast iron gas systems of MichCon and Keyspan. I was an  
236 expert witness for the New Jersey Board of Public Utilities (NJBPU) in its review  
237 of numerous aspects of the gas operation of Public Service Electric & Gas  
238 (PSE&G), including the main replacement program related to the potential  
239 merger of PSE&G and Exelon. As an expert witness, I also reviewed the main  
240 replacement program for and the safety aspects of the gas systems of Yankee  
241 Gas for the Connecticut Department of Public Utilities Control. Currently, I am  
242 conducting the system safety review of Puget Sound Energy for the Washington  
243 Utilities and Transportation Commission.

244  
245 In summary, my background includes 18 years of operating experience in gas  
246 utilities and 12 years of numerous consulting assignments in the gas and electric  
247 utility industries. Many of those assignments, both international and domestic,  
248 were focused on cast iron and ductile iron mains.

249

250 **II. General and Background Information**

251 **Q Would you describe PGL's system as unique?**

252 **A Yes.**

253

254 **Q Why? Please explain in detail.**

255 A PGL has been the sole distributor of natural gas to the people of Chicago for  
256 approximately 150 years. PGL's pioneering history as a manufactured gas  
257 system, creating gas from coal and supplying it primarily for use as lighting, has  
258 resulted in the remaining legacy low-pressure gas distribution system, a subject  
259 that I will address at length in my testimony.

260

261 The provision of natural gas service for the residential, commercial,  
262 transportation and industrial customers of Chicago is indeed a unique  
263 responsibility.

264

265 As the largest city in the United States with a continental climate, the climate and  
266 geography of Chicago affords strong factors that could adversely affect pipe  
267 integrity. They include poorly drained soils, large temperature variations, and  
268 conditions favorable for frost heave, which is when soil expands and contracts  
269 due to freezing and thawing.

270

271 PGL's long and pioneering history of service to Chicago has also resulted in  
272 several other unique characteristics. PGL has the most miles of ductile iron pipe  
273 used for natural gas distribution in the United States. The PGL system has the  
274 second largest combined mileage of cast iron and ductile iron main as a percent  
275 of total miles of main of any gas operator in the United States and the fourth

276 greatest combined mileage of cast iron and ductile iron main. Exhibit SDM-1.2  
 277 identifies the top 11 utilities with CI and/or DI pipe.

278

283

284 **Q Please describe the current distribution system infrastructure that PGL**  
 285 **maintains and operates. What are the physical characteristics and material**  
 286 **make up of PGL's current distribution system?**

287 **A** PGL receives odorized gas from four city gate stations, where gas volumes are  
 288 measured and the pressure is reduced to distribution pressure. My testimony  
 289 does not discuss the interstation high-pressure network.

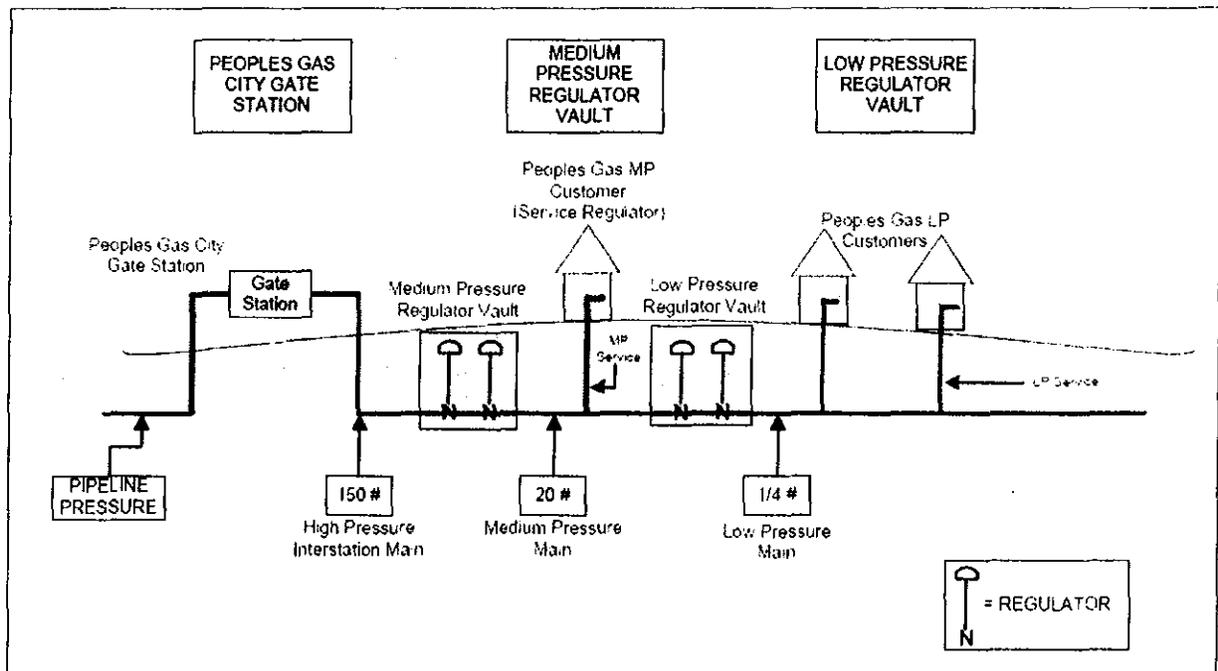

290

291 PGL operates an integrated gas distribution network comprised of medium-  
 292 pressure and low-pressure systems. Exhibit SDM-1.3 illustrates the major  
 293 components of PGL's distribution network. The 1,848 mile medium-pressure

294 system, approximately 47 percent of the distribution network, is operated at a  
295 pressure of 20 pounds per square inch (psig) with a maximum allowable  
296 operating pressure (MAOP) of 25 psig. The 2,155 miles of low-pressure system,  
297 approximately 53% of the distribution network, is normally operated at  
298 approximately 0.25 psig (6 inches of water column). The low-pressure system's  
299 MAOP is 0.5 psig, or 12 inches of water column. The step-down in pressure from  
300 medium-pressure to low-pressure occurs at district regulator stations. The low-  
301 pressure system is supplied by approximately 345 medium-pressure to low-  
302 pressure district regulator stations. Main lines transport gas from the regulator  
303 vaults to individual medium- and low- pressure customers via individual service  
304 lines. In all, PGL operates and maintains approximately 4,000 miles of medium  
305 and low-pressure gas distribution main, and 508,475 service lines.

306

307 **Exhibit SDM -1.3 - Illustrations of Distribution System Pressure Components**

308

309 Exhibit SDM-1.4 shows the material makeup of PGL's distribution system,  
 310 according to its 2008 report to the U.S. Office of Pipeline Safety, which contains  
 311 system data for year-ending 2007.

314

315 Often a service line feeds multiple meters. PGL has about 540,678 meters  
 316 installed inside buildings.

317

318 **Q How does PGL's distribution system infrastructure compare to those of**  
 319 **other utilities in the United States, particularly those in major urban areas**  
 320 **such as the City of Chicago?**

321 **A** Chicago is a world class cultural and commercial city, and likely site of the 2016  
 322 Olympic Games. It is therefore instructive to compare PGL's system with the  
 323 five largest cities in the United States (Exhibit SDM- 1.5). This comparison shows  
 324 that on a per mile basis PGL has the highest percentage of cast iron and ductile  
 325 iron mains. This phenomenon is at least partially explained by PGL's history of  
 326 approximately 150 years as a pioneering gas distribution company.

327

330

331 **Q What is entailed in operating and maintaining a distribution system**  
 332 **infrastructure like PGL's distribution system?**

333 **A** Although the federal and state pipeline safety regulations establish minimum  
 334 safety standards, operating and maintaining the integrity of legacy assets such  
 335 as cast iron and ductile iron pipe in a large, urban environment necessitates the  
 336 effective implementation of a robust Operating and Maintenance ("O&M") Plan of  
 337 policies, processes and procedures. The breath and depth of PGL's plan is

338 expansive because of the diversity of pipe materials (cast iron, ductile iron, steel,  
339 polyvinyl chloride, copper and polyethylene) and operating pressures (low-  
340 pressure and medium-pressure). The prevention and mitigation activities in the  
341 plan include, but are not limited to:

- 342 • Instrument surveys for leaks and corrosion;
- 343 • Patrolling for excavation activities;
- 344 • Inspection of exposed pipe and other facilities;
- 345 • Preventative maintenance;
- 346 • Repair, rehabilitation or replacement;
- 347 • Inside safety inspections;
- 348 • Damage prevention programs; and
- 349 • Emergency response.

350  
351 The frequency of PGL's scheduled surveys, inspections, patrols and  
352 maintenance range from weekly to once every 10 years.

353  
354 **Exhibit SDM-1.6 – Frequency of Surveys and Inspections**

356

357

358 **Q In your testimony, you frequently refer to risks and the potential failure of**  
359 **cast iron and ductile iron. What are the inherent risks associated with each**  
360 **of these materials and their failure mode?**

361 **A** As the gas industry has evolved, so have the types of materials used in  
362 constructing gas distribution systems. The majority of pipe in PGL's gas  
363 distribution system is cast iron, ductile iron, steel, or plastic. It is evident in  
364 Exhibit SDM-1.4 that among its "peer" gas distribution utilities, PGL is the only  
365 entity with CI/DI service pipes in its system. This is largely due to PGL's long and  
366 unique history described above. The failure mode of these various pipe  
367 materials directly influences the principal risk associated with the integrity of the  
368 gas mains - the risk of injuries, fatalities and damage to property caused by gas  
369 releases and potential subsequent explosions.

370

371 For cast iron pipe, pipe fractures are the primary mode of failure resulting in the  
372 risk of an incident. Cast iron pipes fracture circumferentially (around the pipe) or  
373 axially (along the pipe) depending on the pipe diameter, extent of corrosion and  
374 external stresses. The operating pressure of cast iron pipes, which produces  
375 internal stress, is not a factor here because of the relatively low operating  
376 pressure of the cast iron distribution system. Circumferential fractures tend to  
377 result in catastrophic failure caused by ground movement that result in stress  
378 exceeding beam strength of the pipe causing the pipe to break in two pieces.  
379 While cast iron, like all materials, will eventually fail, cast iron failure is not time  
380 dependent, making it impossible to predict when a cast iron pipe will fail.

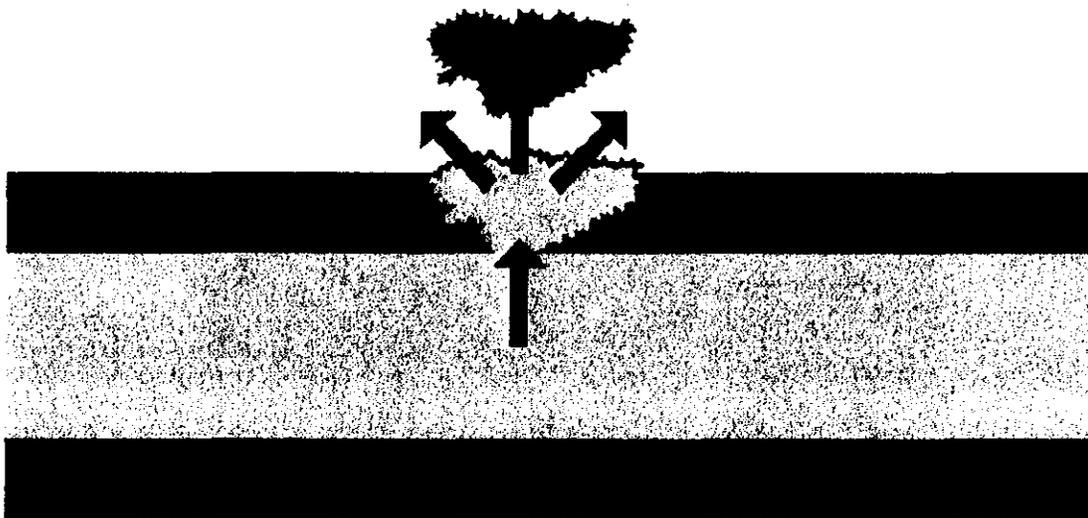

381  
382 With respect to ductile iron pipe, plug failures are the primary mode of failure  
383 resulting in the risk of an incident. In ductile iron pipe, a hole or plug (typically the  
384 size of a dime or larger) will suddenly give way. This is illustrated in Exhibit SDM-  
385 1.7. The operating pressure of ductile iron pipes, which produces internal stress,  
386 combined with the corrosion of the pipe wall are factors in the likelihood of a plug  
387 failure. While ductile iron pipe failure is time dependent, failures are sudden and  
388 unpredictable. These failures can be similar to or worse than cast iron fractures.  
389 Ductile iron failures present a significant risk to personnel working on exposed  
390 ductile pipe, as the pipe can fail without warning. The use of cast iron risk  
391 models for ductile iron main is inappropriate due to the different mode of failure.

392

393

394  
395

### Exhibit SDM-1.7 - Plug Failure of Ductile Iron Pipe

396

397 **Q What materials would PGL be using to replace the cast iron and ductile iron**  
398 **in its distribution system under the accelerated replacement program?**

399 A Polyethylene pipe materials and coated cathodically protected steel, which  
400 currently represent the state-of-the-art in gas main and service materials, will be  
401 used.

402

403 **Q Please discuss the approaches that gas distribution operators utilize to**  
404 **manage cast iron and ductile iron pipe systems.**

405 A One method gas distributors use to manage failing CI/DI pipe is to repair leaks  
406 aggressively. This approach can be perceived as a "Band-Aid" approach that  
407 provides no proactive, systematic improvements by replacing the CI/DI with  
408 modern pipe materials.

409 The preferred method of managing CI and DI pipes is to replace these materials  
410 by using a combination of three approaches: condition, enforced and plan. This  
411 method provides for a long-term, proactive, systematic improvement of a  
412 company's distribution network.

413  
414 The condition approach for identification and removal of CI/DI pipes is similar to  
415 the approach recommended by previous independent studies done for PGL  
416 (Zinder Engineering, Inc. 1981, 1994, 2002; Kiefner and Associates, Inc. 2007).  
417 Individual segments may be evaluated on such factors as maintenance history,  
418 soil conditions, and risks inherent in the pipe segment's location.

419  
420 The enforced approach entails the removal or replacement of pipes in  
421 conjunction with the needs of the City of Chicago, or other applicable  
422 governmental agency, to accommodate public work projects such as road  
423 improvements and water infrastructure projects. It is beneficial to all parties  
424 involved if the removal and replacement of pipes can be done in conjunction with  
425 other projects, especially to minimize public inconvenience and to avoid the  
426 duplication of efforts. The plan approach, as I will more fully demonstrate in my  
427 testimony, involves systematic replacement of large contiguous areas of low-  
428 pressure and medium-pressure cast iron and ductile iron main while reducing the  
429 system risk, creating the best economic efficiencies for construction costs and  
430 also certain operation and maintenance economies.

431

432 In terms of program replacement strategies, some gas distribution operators  
433 have approached their state regulators and obtained funding approval to  
434 systematically replace all of the cast iron or bare steel in their system on an  
435 accelerated basis. For example, in 2006 the New Jersey Board of Public Utilities  
436 (NJBPU) approved Elizabethtown Gas' \$37 million pipeline replacement  
437 program. This is approximately a four-year program to replace about 60 miles of  
438 cast iron gas mains, accelerating efforts over the previous 10 years that resulted  
439 in the replacement of approximately 144 miles of cast iron pipe.

440  
441 In my opinion, comparisons of PGL with the approaches undertaken by other  
442 utilities must be viewed in regard to the large amount of CI and DI pipe and  
443 medium-pressure DI in PGL's system. Also, by following the recommendations of  
444 other independent audits, PGL has not engaged in the systematic removal of  
445 CI/DI pipes on an accelerated basis. I have found that based on the 2008 U.S.  
446 Department of Transportation (DOT) Pipeline and Hazardous Materials Safety  
447 Administration ("PHMSA") Office of Pipeline Safety ("OPS") Annual Reports filed  
448 by PGL and other gas utilities, PGL ranks second out of 1426 operators across  
449 the nation in terms of percentage of CI/DI as compared to total miles in its  
450 system. PGL also ranks first for miles of DI in its system and fourth in total miles  
451 of CI & DI combined. In terms of *service* lines with CI/DI, PGL ranks fifteenth for  
452 CI, first for DI and ninth for combined CI & DI in its system. These high rankings  
453 must be viewed in contrast to the fact that PGL ranks thirty-first in terms of total  
454 number of services.

455 **Q In your opinion, does PGL currently operate and manage a system that is**  
456 **deemed safe by industry standards?**

457 **A** In my opinion, within the constraints of not having an accelerated replacement  
458 program, PGL's operation and management of its distribution system currently  
459 provides a level of safety that compares well to industry standards, including  
460 other utilities with a large amount of CI/DI in their systems.

461

462 As shown in Exhibit SDM-1.8, PGL's leak rate for services per mile is below the  
463 national average, and above the national average for main leaks per mile.

480

481

482

483

484

485

486

A recent (2008) independent safety audit by the Liberty Consulting Group, which compared PGL to other utilities having a considerable amount of CI/DI mains in their system, determined that PGL ranked well below the median in terms of the number of leaks repaired, and PGL was well above the median in backlog of leaks to be repaired.

487 PGL's leak rates compare well with the other 10 systems in the industry with the  
 488 most amounts of CI/DI pipes in their systems. (See Exhibit SDM-1.9) However,  
 489 as is the case with all of these utilities having CI/DI pipes, PGL's leaks per mile of  
 490 main is above the national average, as reported in OPS Annual Reports.

| NATIONAL AVERAGE                        | 107              | 233                 | 842                 | 45,450              | 0.13                        | 0.51                          |

493  
 494  
 495 With regard to other independent audits of PGL's safety relative to CI and DI  
 496 mains (Zinder Engineering, Inc. 1981, 1994, 2002; Kiefner and Associates, Inc.  
 497 2007), it is my opinion that PGL has acted responsibly to meet CI/DI  
 498 recommendations contained in the reports. I find that PGL has undertaken  
 499 reasonable and innovative operations and management techniques to achieve  
 500 compliance with all recommendations in undertaking the unique task of operating  
 501 and managing such a relatively large amount of CI and DI pipe.

502  
 503 However, based on industry experience, the unpredictable nature of DI pipe and  
 504 PGL's backlog of leak repairs in its system, it is my opinion that an accelerated

505 replacement effort by PGL will be required to maintain or improve the safety of its  
506 system.

507

508 **Q In your opinion does the current program main or service line replacement**  
509 **duration present any risks to PGL or its customers?**

510 A Yes. While there is no immediate risk posed by PGL's current system and  
511 operating practices, the system is aging and, while PGL does a good job  
512 managing the risks posed by its antiquated system, all materials will eventually  
513 fail and require replacing. Moreover, the costs associated with the ongoing  
514 management of the risk posed by an aging system likely will increase as the  
515 system continues to age. For example, the rate of ductile iron failures in other  
516 gas distribution systems has been shown to increase with age. PGL has more  
517 ductile iron than any other gas distribution system in the U.S.

518

519 PGL's plan is one that is proactive and would allow it to stay ahead of any such  
520 potential failures or increased risk management expenses. If in the future,  
521 however, failures which could pose a risk to the general public manifest  
522 themselves, a reactive acceleration of the replacement program at that time  
523 could present costly and difficult management issues as opposed to a more  
524 proactive planned approach, such as the one proposed in this testimony.

525

526 **Q In your opinion, will an accelerated program to replace the low-pressure**  
527 **main and service line infrastructure mitigate those risks and improve the**  
528 **safety aspects of PGL's distribution system?**

529 A Yes. An accelerated program to replace the low-pressure system main and  
530 service line infrastructure would result in the replacement of 1,427 miles (86.3%)  
531 of CI pipe, and 238 miles (75.8%) of the DI pipe. Together with the removal of the  
532 remainder of the CI/DI pipe, which is in the medium-pressure system, these  
533 actions would, in my opinion, further mitigate future risks to PGL and its  
534 customers and avoid a potential reactive approach in the future. It is my opinion  
535 that a potential unpredictable failure or series of failures could precipitate a  
536 reactive approach to accelerating the replacement of these materials and would  
537 impact negatively all the benefits and advantages of pursuing a planned program  
538 like the accelerated replacement program being proposed in this testimony.

539  
540 One example of a precautionary approach to accelerated replacement of low-  
541 pressure and medium-pressure higher-risk pipe is the actions taken by Transco  
542 (now National Grid) in the United Kingdom. Following a review of Transco's risk-  
543 based methodology, the UK Health and Safety Executive (HSE), which has  
544 national pipeline safety responsibility, no longer considered the risk-based  
545 program to be an acceptable course of action because it:

- 546 • Did not constitute adequate action to comply with the requirements of health  
547 and safety legislation; and
- 548 • Did not address the likelihood and severity of health and safety (and social  
549 and economic) consequences should a rapid deterioration of the network  
550 occur.

551

552 In 2001 the HSE and the Office of Gas and Electricity Markets (OFGEM), which  
553 has price control responsibilities, required Transco to complete replacement of  
554 48,625 miles of cast iron and 8,125 miles of ductile iron within 30 years. At the  
555 previous replacement rate, it would have taken 51 years. The HSE keeps the  
556 replacement policy under review as program implementation proceeds.

557

558 **Q In addition to accelerating the replacement of higher-risk materials, are**  
559 **there any additional safety benefits that PGL's proposed system would**  
560 **provide?**

561 **A** Yes, there are many safety benefits that can be realized in addition to the  
562 elimination of the catastrophic fractures associated with cast iron pipe and the  
563 unpredictable plug failure of ductile iron pipe.

564  
565 Replacing the low-pressure system will enable PGL to install excess flow valves  
566 on customer service lines. An excess flow valve is a device installed on the  
567 service line at the point where the service line is connected to the main. In the  
568 event that the service is cut, the sudden pressure drop and increased flow rate  
569 causes the device to be activated, stopping further escape of gas. Excess flow  
570 valves cannot be installed on low-pressure systems because the pressure  
571 difference between the pressure in the gas main and atmospheric pressure is  
572 insufficient for the devices to function.

573

574 The elimination of the low-pressure system will enable PGL to simplify its  
575 operating and maintenance plan. For example, medium- to low-pressure district  
576 pressure stations will be eliminated, increasing standardization of procedures and  
577 reducing the potential of operator error.

578  
579 Unlike the low-pressure system, a medium-pressure meter set will have a  
580 pressure regulator with overpressure relief and a meter shutoff valve installed  
581 before the meter. The meters that are relocated from inside to outside will  
582 eliminate the need for inside safety inspections. However, PGL will still  
583 respond to inside gas odor calls from customers. Outside meters will also  
584 enable the City of Chicago Fire Department to quickly shut off gas to the  
585 property from the outside.

586  
587 Eliminating the low-pressure system will reduce the size and duration of  
588 unplanned gas outages. Outages caused by water infiltration will be virtually  
589 eliminated. The use of polyethylene (PE) main will enable PGL crews to  
590 isolate gas leaks quickly for repair by either closing an existing valve or  
591 squeezing the pipe off upstream and downstream of the leak.

592 Other safety improvement associated with the replacement program is the  
593 opportunity to move gas facilities away from other utility infrastructure in the  
594 street, such as water and sewer lines, by moving gas lines into the parkway. This  
595 is expected to result in a reduction of excavation damage and an increase in  
596 worker safety.

597

598 Customers who currently require elevated pressure but are served from the low-  
599 pressure system must install and maintain gas boosters and safety back-check  
600 valves. Gas boosters and safety back-check valves present an operating risk to  
601 both the customer and PGL. If these devices should fail, it could result in  
602 damages to both the customer and PGL facilities. Switching these customers  
603 from a low-pressure to a medium-pressure source of gas supply will enable many  
604 of these customers to remove their gas boosters and safety back-check valves.

605

606 **Q Does the need for infrastructure replacement reflect any unique and**  
607 **unpredictable circumstances?**

608 **A** I previously described the unique and unpredictable circumstances of PGL's gas  
609 distribution system in various questions above. These circumstances are  
610 summarized below:

- 611 • Large urban operator in a large, world-class city
- 612 • Climatic conditions that pose challenges to infrastructure
- 613 • Large amount of DI medium-pressure pipe
- 614 • Large amount of low-pressure cast iron
- 615 • Failure modes of CI and DI material

616

617 The risk associated with cast and ductile iron failure increases with pressure.

618 PGL has approximately 16% of its cast and ductile iron pipe operating at

619 medium-pressure; this is more than Public Service Electric and Gas, which has  
620 the largest cast and ductile iron system in the U.S.

621

622 **III. Modernization and Technology**

623 **Q What are the strengths and weaknesses of the type of materials used for**  
624 **mains and services in PGL's existing distribution infrastructure system**  
625 **that would be replaced under the proposed accelerated program?**

626 **A** In my response earlier, I discussed the failure modes of the "at-risk" materials.  
627 The use of PE pipe will eliminate the threat to pipe integrity associated with  
628 corrosion of iron pipe and stress-related cracking of pre-1980 plastic pipe  
629 material. PE, which is also less expensive to install and maintain than coated  
630 cathodically protected steel pipe, has a longer life expectancy of 80 plus years.

631

632 However, there are situations where the material strength and gas capacity of  
633 coated, cathodically protected steel pipe will be necessary. The appropriate  
634 material will be determined when a project is designed.

635

636 **Q In your opinion, what are the strengths and weaknesses inherent in a low-**  
637 **pressure gas distribution system such as the one that would be replaced**  
638 **under the proposed accelerated program?**

639 **A** The low-pressure system is a legacy from the period when gas was  
640 manufactured from coal. When natural gas became available, the existing  
641 system was converted to a low-pressure natural gas distribution system. No new

642 (Greenfield) gas distribution system would consider constructing a low-pressure  
643 distribution system today.

644

645 In my opinion, a low-pressure system provides no compelling benefits.

646

647 **Q What are the strengths and weaknesses inherent in a medium-pressure gas**  
648 **distribution system such as the one to which PGL plans to upgrade in the**  
649 **proposed accelerated replacement program? How do they compare to the**  
650 **existing system it would replace?**

651 **A** A medium-pressure natural gas distribution system has many benefits. To begin  
652 with, it is less costly to construct because the operating pressure allows smaller  
653 diameter pipe to be installed. A medium-pressure system can be constructed of  
654 PE pipe, which is less expensive than coated steel pipe.

655

656 From an operating and maintenance perspective, a medium-pressure system  
657 has fewer joint leaks because the PE pipe is fused and steel pipe is welded. The  
658 gas flow in a PE pipe can be shut-off as quick as or quicker than a low-pressure  
659 system by squeezing the PE pipe.

660 When a leak occurs on a medium-pressure system, all else being equal,  
661 additional gas will escape than from a low-pressure system. This does not  
662 necessarily mean that a leak on a medium-pressure system is more likely to  
663 result in a reportable incident. Often a leak on a medium-pressure system is  
664 reported sooner, and it is easier to locate the source of the leak. A medium-

665 pressure system also generates fewer calls from customers with appliance  
666 problems caused by insufficient gas pressure.

667

668 **Q Can you cite other systems which are undergoing modernization?**

669 A The following is a list of companies that are undergoing modernization, based on  
670 the American Gas Association ("AGA") Rate Round-Up Newsletter of December  
671 2007 and a Jacobs Consultancy telephone survey. This list was compiled by the  
672 participating AGA panel of companies and may not be a total list of U.S.  
673 companies undertaking modernization.

674

675 **Exhibit SDM -1.10 - Gas Utilities with Regulatory Approved Asset Replacement Programs**  
 676

| <b>Company Name</b>                    | <b>Type of Modernization</b>                                              |
|----------------------------------------|---------------------------------------------------------------------------|
| CenterPoint Energy Southern Operations | Replacement of Bare Steel Mains, Cast Iron Mains, and Associated Services |
| Atlanta Gas Light                      | Pipeline Replacement Program                                              |
| Vectron South - SIGECO                 | Cast Iron Mains, Bare Steel Mains, & Services Replacement Program         |
| Kansas Gas Service                     | New Infrastructure Replacement                                            |
| Aquila                                 | Replacing of Gas Main                                                     |
| Duke Energy - Cinergy                  | Accelerated Main Replacement                                              |
| Laclede Gas                            | Infrastructure System Replacement                                         |
| Missouri Gas Energy                    | New Infrastructure Replacement                                            |
| Atmos Energy                           | Infrastructure System Replacement                                         |
| Elizabethtown Gas                      | Pipeline Replacement Program                                              |
| National Grid                          | Replacement of Leak-prone Mains                                           |
| Duke Energy                            | Accelerated Main Replacement                                              |
| NW Natural Gas Utilities               | Gas Reliability Infrastructure Program                                    |
| All Natural Gas Utilities              | Gas Reliability Infrastructure Program                                    |
| Atmos Energy                           | New pipes, Replacement Pipe, Pipeline Integrity Capital)                  |
| Texas Gas Service                      | New Infrastructure Replacement                                            |
| Puget Sound Energy                     | Cast Iron Mains, Bare Steel Replacement Program                           |
| Vectren North - Indiana Gas            | Infrastructure System Replacement                                         |
| Columbia NiSource                      | Infrastructure Replacement Program                                        |
| Oklahoma Natural Gas                   | Replacement of Mains and Service Lines                                    |

677  
678

679 **Q Will the new infrastructure system lead to synergies and efficiencies in**  
 680 **system maintenance and operation?**

681 **A** Yes.

682

683 **Q How will those synergies and efficiencies translate into benefits for the**  
 684 **customers?**

685 **A** Customers will benefit from the synergies and efficiencies in system maintenance  
 686 and operation in several ways:

- 687 • Simplify PGL's O&M plan, reducing the cost of maintaining the plan and  
688 associated employee training;
- 689 • Eliminate the inspection and maintenance of medium- to low-pressure  
690 regulator stations;
- 691 • Reduce and possibly eliminate some of the inconvenience and cost of inside  
692 safety inspections;
- 693 • Reduce the amount of pipe leak surveys each year;
- 694 • Reduce the number of emergency calls;
- 695 • Eliminate the freeze-up of low-pressure risers; and
- 696 • Reduce emergency and warehouse inventory.

697

698 **Q Are there any additional reasons why this upgrade to a newer and more**  
699 **modern infrastructure system needs to be accelerated?**

700 **A** Benefits of the medium-pressure system would include incremental services  
701 made possible by the medium-pressure system's ability to accommodate  
702 technologies and appliances not available through the current low-pressure  
703 system, including access to many high-efficiency appliances. In the relatively  
704 near future, the residential low-pressure system may not be able to serve  
705 standard residential appliances, if as expected; they require 6" of water column  
706 pressure at the burner tip. The lack of a medium-pressure system would cause  
707 customers in Chicago to forego consumer options or require more expensive  
708 special orders.

709

710 In addition, a medium-pressure system will allow Chicagoans to install higher

711 efficiency appliances. The following higher efficiency appliances require inlet  
712 pressures that in many cases would require either a customer-installed booster  
713 or PGL's provision of a medium-pressure system:

- 714 • Tankless water heaters;
- 715 • Fan assisted heaters;
- 716 • Home generators; and
- 717 • Commercial-grade cooking appliances.

718  
719 Exhibit SDM-1.11 shows the consumer benefits that could be achieved from the  
720 installation of a tankless water heater. These benefits will not be available to all  
721 customers, unless the system is upgraded to a medium-pressure system.

722

723 **SDM -1.11 – Consumer Benefits of a Tankless Water Heater**

| <b>Water Heater Type</b>               | <b>Water Heater Life<sup>^</sup></b> | <b>Minimum Gas Pressure</b> | <b>Estimated Annual Energy Cost<sup>**</sup></b> |
|----------------------------------------|--------------------------------------|-----------------------------|--------------------------------------------------|
| Tankless Water Heater                  | 20                                   | 4.5" - 7" WC                | \$265                                            |
| Gas 40 Gallon Heater <sup>***</sup>    | 13                                   | 4.5"                        | \$326                                            |
| Electric 40 Gallon Tank <sup>***</sup> | 15                                   | NA                          | \$453                                            |

<sup>\*\*</sup> Based Upon DOE average Energy Costs for 2006

<sup>\*\*\*</sup> Source: GAMA Consumers Directory of Certified Efficiency Ratings

724

725

726 The benefits for commercial applications would also increase. Current

727 commercial kitchen equipment requires a minimum of about 6" of water column,  
728 as do current rooftop heating systems which are standard for commercial use.  
729 Therefore, in many areas, customers must install electric-driven gas boosters to  
730 raise the gas pressure, and back-up systems for the pressure boosters as a  
731 safeguard against electrical power outages. The cost of these booster systems  
732 and back-ups, based on information provided by PGL staff, are between \$20,000  
733 and \$50,000, depending on commercial building size and back-up configuration.  
734 Currently, commercial boilers specifically made for low-pressure system  
735 installation are available from only one manufacturer. Another area of potential  
736 savings for customers is that a medium-pressure system would allow them the  
737 option of using corrugated steel piping, which is more economical and would  
738 allow customers to reduce their building construction costs.

739  
740 Chicago code requires critical facilities such as schools, hospitals, and  
741 emergency services providers to have back-up generation installed. However,  
742 natural gas-fired generator equipment requires medium-pressure or additional  
743 booster and back-up expenses if connected to the low-pressure system in many  
744 locations.

745  
746 In addition to the system safety advantages of replacing the low-pressure system  
747 that I have described above, there are other benefits relating specifically to  
748 natural gas-fired portable generators. Because natural gas-powered back-up  
749 generators require medium-pressure, the alternative is the more dangerous and

750 less environmentally-friendly gasoline- or diesel-powered versions. The use of  
751 gasoline- or diesel-powered emergency generators is less safe than a  
752 permanently connected natural gas-fueled generator, primarily due to the risks  
753 involved in gasoline or diesel fuel storage and transfer, especially in residential  
754 situations.

755

756 **Q Will the upgraded system provide any environmental benefits?**

757 A Conversion of the current low-pressure system to a medium-pressure system  
758 would provide certain environmental benefits. In the upgrading of the system,  
759 the use of directional drilling and insertion construction techniques will reduce the  
760 amount of soil that will need to be removed and disposed. The use of double  
761 decking -- the process whereby the main in the street is replaced with a main  
762 installed in the parkway on both sides of the street -- will reduce future street  
763 excavation, as well as soil removal and disposal. In nearly all cases, the use of  
764 removed spoil is not eligible for use as fill and must be transported and disposed  
765 of in a landfill. Additionally, once the pipes are replaced, the carbon footprint of  
766 PGL's maintenance program would be reduced because much fewer  
767 maintenance trips by crew vehicles would be required.

768

769 PGL's proposed conversion from an low-pressure to medium-pressure system  
770 with replacement of CI/DI mains would also bring about a significant reduction in  
771 natural gas leaked to the atmosphere. According to a 1996 study by the U.S.  
772 Environmental Protection Agency, the largest contributors to the overall annual

773 emissions from natural gas distribution systems were cast iron mains. Exhibit  
774 SDM-1.12 illustrates how the reduction in emissions was calculated.

775

776 **Exhibit SDM -1.12 - Greenhouse Gas Emission Reductions**

| Material:                 | Emissions Factor:   |
|---------------------------|---------------------|
| Mains - Cast Iron         | 238.7 Mcf/mile/year |
| Mains - Unprotected Steel | 110.5 Mcf/mile/year |
| Mains - Protected Steel   | 3.13 Mcf/mile/year  |
| Mains - Plastic           | 9.91 Mcf/mile/year  |

Calculating of Emission Reduction (ER) for distribution systems replacement, using example of current replacing 45 miles of cast iron with 22.5 miles of steel and 22.5 miles of plastic is as follows:

ER = Emission Reduction

$$ER = (Miles_{CI} \times EF_{CI}) - (Miles_{Steel} \times EF_{Steel}) - (Miles_{Plastic} \times EF_{Plastic})$$
$$ER = 45 \times 238.7 - 22.5 \times 3.13 - 22.5 \times 9.91$$
$$ER = 10,448.1 \text{ Mcf/year}$$

777

778 Therefore, applying the study to PGL's current replacement rate of 45 miles of CI  
779 pipe per year is resulting in reduced greenhouse gas emissions of 10,448 Mcf<sup>1</sup>  
780 per year. Doubling the rate of replacement of the 1,929 miles of CI/DI pipe in the  
781 low-pressure system would result in a reduction of nearly 21,000 Mcf per year.

782

783 Another environmental benefit of the conversion from a low-pressure to a  
784 medium-pressure system is the nearly complete reduction in the amount of water  
785 which would be collected from the distribution system. CI joints are prone to  
786 leaking and the water that enters the system pipes needs to be collected and  
787 removed. The locations where this water is collected are known as "drips". Drip

<sup>1</sup> "Mcf" is a unit of measure equaling a thousand cubic feet of natural gas.

788 collection on PGL's low-pressure system is done routinely and especially after  
789 rains. The water is collected and taken to PGL's Crawford facility where it is  
790 tested for contaminants. When contamination is found, it occurs in the form of  
791 PCB contamination that has been received from the interstate pipelines which  
792 provide gas to PGL's system.

793  
794 The water collected from drips is treated and disposed of depending on whether  
795 it is contaminated. This process would be virtually eliminated in an medium-  
796 pressure system because newer pipe and joint materials would be much more  
797 impervious, and the medium-pressure of the gas would keep the water from  
798 entering the system.

799  
800 The conversion to a medium-pressure system would also facilitate the use of  
801 higher-efficiency gas appliances such as those described previously in my  
802 testimony. The use of higher-efficiency appliances means that smaller volumes  
803 of gas are consumed to produce the same amount of therms when compared to  
804 standard appliances, providing for conservation of natural gas supplies. For  
805 example, according to the American Council for an Energy Efficient Economy's  
806 Consumer Guide to Home Energy Savings, a high efficiency gas water heater  
807 can perform at an annual fuel efficiency rating of 80%, compared to 60% ratings  
808 for conventional gas water heater.

809 **IV. Identification and Description of New System's Functionalities**

810 **Q How will the operating and maintenance functionalities of the system differ**  
811 **following the system modernization?**

812 **A** The gas pressure customers receive will be controlled more accurately and will  
813 enable PGL to accommodate customers that require elevated-pressure without  
814 the customer needing to install gas boosters. The medium-pressure will prevent  
815 water infiltration into the gas mains, eliminating the collection of liquids covered  
816 by environmental regulations governing the collection, transport and disposal of  
817 those liquids. There will be fewer district pressure regulators to monitor, inspect  
818 and maintain. The use of PE pipe will enable quicker and safer isolation and  
819 repair of mains.

820  
821 In my opinion, there are no beneficial functionalities of the low-pressure system  
822 that will be foregone.

823  
824 **Q Please identify and describe the functionality of the new system beginning**  
825 **in 2009 from a system operation perspective.**

826 **A** The system will be connected to two new city gate stations, six total, which will  
827 provide additional reliability and provide a more optimal design. Operating the  
828 system will be simplified. All 345 medium to low-pressure regulator stations will  
829 be eliminated. The 54 new high-pressure to medium-pressure regulator stations  
830 are expected to have a common design reducing construction costs and future  
831 maintenance costs. Outages caused by water infiltration will no longer occur.

832 This is especially important in winter months when conditions can lead to water  
833 main breaks at the same time that gas delivery for heating is crucial.

834  
835 Additional capacity to existing customers could be accommodated by increasing  
836 the allowable operating pressure. Where possible, PE pipe in residential areas  
837 will be double decked – installed in the parkway on both sides of the street –  
838 reducing the amount of pipe beneath streets. This configuration also potentially  
839 may reduce excavation related damage and minimize maintenance costs. This  
840 will also result in benefits to the City of Chicago as PGL's pipes will be less likely  
841 to be encountered during street repairs or other utility activities. Additional valves  
842 will be available to isolate portions of the system, as well as create the ability to  
843 isolate smaller sections by use of squeeze off. Meter sets relocated outside  
844 provide greater access and improved safety. The volume of gas a customer uses  
845 will be metered more accurately because the gas volume will be temperature  
846 compensated and measured at a constant pressure. Company personnel will be  
847 able to shut-off gas to buildings in emergencies or for non-payment without the  
848 customer being present.

849  
850 **Q Please identify and describe the functionality of the new system from a**  
851 **system maintenance perspective.**

852 **A** Where possible, the new regulator stations may be located in the parkway  
853 providing safe access and reduced impact on traffic. Elimination of a class of  
854 regulator stations - medium-pressure to low-pressure – will reduce the amount of  
855 training, inspection and maintenance, and therefore reduce the potential of

856 human error. Overall, the City of Chicago will encounter far fewer regulator  
857 vaults that would impede in-street construction.

858  
859 All steel pipes will be coated and cathodically protected. The increased  
860 proportion of PE to non-PE pipe will reduce the threat of leaks caused by  
861 corrosion and reduce the amount of pipe required to be leak surveyed annually.  
862 Outside meter sets will be readily accessible to both gas company personnel and  
863 City of Chicago emergency response personnel. Outside meters also can  
864 reduce the potentially unsafe theft of gas.

865

866 **Q Please identify and describe the functionality of the new system from a**  
867 **system customer perspective.**

868 A Operating a medium-pressure system will increase reliability over the low-  
869 pressure system. Customers currently on the low-pressure system requiring  
870 elevated pressures will no longer incur the cost of installing, operating and  
871 maintaining gas boosters and safety back-check valves. When practical, service  
872 lines will have excess flow valves, reducing the potential property damage  
873 caused by a damaged service line. Customers will be able to purchase gas  
874 utilization equipment, e.g. gas boilers, without paying equipment premiums due  
875 to the minimum gas pressure. Customers will be able to choose from new or  
876 more efficient gas appliances, e.g. tankless water heaters. The City of Chicago  
877 Fire Department will be able to shut off gas to a building from the outside meter  
878 sets, potentially reducing property damage.

879

880 **Q In your opinion, will the new system involve any foregone functionality?**

881 **A** In my opinion, eliminating the low-pressure system and high risk pipe will not  
882 result in any foregone functionality.

883

884 **V. Benefit to Customer – Cost/Benefit Analysis**

885 **Q Please describe PGL's current distribution pipe replacement programs.**

886 **A** PGL's pipe replacement program consists of three elements: condition  
887 replacement, block replacement and enforced replacement. For condition  
888 replacement, PGL utilizes its Main Ranking System to identify and prioritize gas  
889 main segments as candidates for replacement. Each individual segment is  
890 evaluated based on its maintenance history. Criteria taken into account include  
891 breaks, cracks at taps, pipe wall thickness based on pipe coupons (segments of  
892 pipe removed for testing), visual observation, incidence of leak and other repairs.  
893 Each of these criteria is assigned a factor based on "Break Equivalents" which is  
894 then multiplied by the number of occurrences.

895

896 The sum of the aforementioned numerical values is then multiplied by a factor  
897 based on pipe material, operating pressure, diameter, street type and pavement  
898 cover. The result of this calculation is a value that is assigned to each segment  
899 known as the Main Ranking Index (MRI). The MRI value is rounded to the  
900 nearest quarter point, (i.e. The Uniform Main Rank Index (UMRI)) and sorted in  
901 descending order in order to identify those segments with the highest incidence  
902 of UMRI points per block. In addition, a locational factor is also added. Segments

903 with breaks in the low-pressure system are multiplied by 1 and those with breaks  
904 in the medium-pressure system are multiplied by 2.

905  
906 All segments that have accumulated a UMRI rating greater than 6.0 are placed  
907 on a schedule to be retired. Segments with a UMRI value greater than 3.0 are  
908 viewed as possible replacement candidates when performing work on adjacent  
909 segments and when evaluating the extent of Public & System Improvement  
910 projects.

911  
912 For block replacements, PGL recently developed a Cost Optimization Program  
913 (COP) in order to calculate and generate savings from future maintenance costs  
914 avoided by replacing pipe when needed. This program's goal is to create  
915 savings for customers and shareholders by reducing investment in repairs by  
916 replacing facilities on a timely basis. Using very detailed information on 80,000  
917 pipe segments that is integrated with the representation of PGL's distribution  
918 system in its computerized geographic information system, the COP creates  
919 groupings where greatest future maintenance costs would be avoided by  
920 replacement.

921  
922 PGL has inserted smaller-diameter plastic pipe in CI/DI pipes where feasible due  
923 to sufficient length of line without service connections being present. The  
924 remaining CI and DI mains would be in most cases abandoned in place,  
925 necessitating the reconnection and replacement of service lines. The existing

926 service lines to be replaced are primarily plastic, cast iron, and copper. They are  
927 to be replaced by plastic service lines. If the low-pressure system were replaced  
928 by a medium-pressure system, low-pressure regulator vaults would no longer be  
929 needed and would be removed.

930  
931 At the current rate, replacement of all segments of 10-inch and 12-inch diameter  
932 CI/DI pipe should be completed by 2050, and replacement of all segments of 16-  
933 inch and larger CI/DI pipe should be completed by 2080.

934

935 **Q What is the current approach utilized for determining pipe replacement**  
936 **goals by PGL?**

937 **A** As I stated in my answer to the previous question, PGL currently utilizes methods  
938 and systems to analyze and select potential distribution system capital  
939 improvement projects, based on a combination of pipe history and situational  
940 factors, as well as outcomes of the COP. The methodology for project selection  
941 ranges from the highest potential projects to improvement recommendations  
942 from PGL's general supervisors based on their knowledge of distribution system  
943 weaknesses in their territories to projects based on coordination with public  
944 improvement projects. The driver for determining the location and scope of these  
945 projects has been primarily based on the goal of retiring 45 miles of CI/DI pipe  
946 each year in the most effective manner possible.

947

948 **Q How was the basis for the proposed accelerated replacement period**  
949 **determined?**

950 A Scenario 3 of our cost benefit analysis model represents the proposed  
951 accelerated replacement period. To determine the accelerated replacement  
952 period, we ran Scenario 3 using three different replacement completion years:  
953 2025, 2030, and 2035. The estimated construction costs and O&M savings that  
954 each completion year is expected to produce, as shown in Exhibit SDM-1.13 and  
955 Exhibit SDM-1.14, were analyzed. The replacement rate or miles of main  
956 abandoned per year and the average miles of main installed per year varied  
957 depending on the completion year as shown in Exhibit SDM-1.15. Although  
958 completing the replacement program in 2025 is estimated to produce the most  
959 savings, replacing 154 miles of main per year is more than three times the  
960 current replacement rate and deemed not practical in my opinion, which is  
961 corroborated by PGL operations management. Of the three completion years,  
962 2035 is estimated to produce the least amount of cost savings. As a result, the  
963 completion year of 2030 was chosen based on the feasibility of its replacement  
964 rate and its overall cost benefits.

974  
 975  
 976 **Q Were you able to perform a cost-benefit analysis comparing the current**  
 977 **replacement program to the proposed accelerated replacement program?**

978 **A Yes.**

979 **Q Can you summarize your cost-benefit analysis and its conclusions?**

980 **A** The cost-benefit analysis compares the capital and O&M costs for the proposed  
 981 accelerated program versus the current main replacement program to  
 982 demonstrate that shortening the time frame for completing the main replacement  
 983 program would decrease overall cost, because more current dollars will be used  
 984 for capital. In addition, the cost benefit analysis estimates the benefits that PGL  
 985 can accrue from enhanced investment to replace cast iron and ductile iron main  
 986 in terms of the value of the savings in operating and maintenance expense that  
 987 would be expected to occur as a result of such accelerated replacement. The

988 model not only estimates the total capital cost and O&M cost for the entire  
989 accelerated program, but also presents schedules for capital investment and  
990 O&M expenditures on a yearly basis to show when certain capital investments  
991 are expected to occur and how the savings may vary during the replacement  
992 time period.

993  
994 The cost benefit analysis concluded that there is a net benefit from the  
995 accelerated investment in cast iron and ductile iron main replacement for PGL,  
996 based on the assumptions in our analysis and the estimates of certain key  
997 parameters provided by PGL. According to the 2030 Case, the accelerated  
998 replacement program has economic value to PGL's customers because it is  
999 estimated that the proposed program will result in approximately \$432 million in  
1000 construction cost savings and \$244 million in future O&M cost savings to  
1001 implement the main replacement program in a shorter time frame. The results of  
1002 the cost benefit analysis are summarized in Exhibit SDM-1.16 and Exhibit  
1003 SDM-1.17. The cumulative savings resulting from the proposed accelerated  
1004 program on a yearly basis are shown in Exhibit SDM-1.18.

1005  
1006 As discussed later in my testimony, we have included additional costs associated  
1007 with program management and additional labor for meter work, as well as  
1008 training and professional development. These costs are referred to as  
1009 Incremental O&M ("IOM"). The IOM for the 2030 Case is shown in Exhibit  
1010 SDM-1.19.

Exhibit SDM -1.19 – Incremental O&M

| Estimated Accelerated Program Incremental O&M           |  | 2030                   |
|---------------------------------------------------------|--|------------------------|
|                                                         |  | Scenario 3<br>Proposed |
| Program Management <sup>1</sup>                         |  | \$ 123,374,346         |
| Additional Labor                                        |  | \$ 36,371,092          |
| <b>Total Incremental O&amp;M Cost<sup>2</sup> (IOM)</b> |  | <b>\$ 159,745,438</b>  |
| <b>Incremental O&amp;M Cost/Mile</b>                    |  | <b>\$ 74,060</b>       |
| <b>Incremental O&amp;M Cost/Year</b>                    |  | <b>\$ 8,407,655</b>    |

<sup>1</sup> Program management includes project delivery strategies; management of design, and construction phase activities; cost control; schedule management; document control; and quality assurance.

<sup>2</sup> These costs are not included in the Construction and O&M Costs.

1021

1022 **Q Please describe the factors considered in the cost analysis.**

1023 A The factors considered in the cost analysis are summarized in Exhibit SDM-1.15

1024

1025 **Q What asset replacement strategies (maintenance, reactive, proactive) were**  
 1026 **considered?**

1027 A Maintenance-based replacement strategies have been recommended by past  
 1028 studies, including Zinder Engineering, Inc. and Kiefner and Associates, Inc.,  
 1029 which are primarily focused on maintaining or modifying current rates of pipe  
 1030 replacement. The replacement strategies these studies propose include  
 1031 completion dates as late as 2080 for certain pipe diameters. Such strategies  
 1032 often lead to reactive replacement when segments that have not been replaced  
 1033 pursuant to the planned schedule become problematic. However, as described  
 1034 in the Liberty Consulting Group audit and my previous testimony, PGL's  
 1035 adherence to the recommendations of Zinder Engineering, Inc. and Kiefner and  
 1036 Associates, Inc. has resulted in an unacceptable backlog of leaks carried over to  
 1037 the next year. Most of these leaks are related to CI pipes. As I stated previously,

1038 the uniqueness of PGL's system and the unpredictability of CI and especially DI  
1039 pipe in regard to potential failure, points to a proactive pipe replacement program  
1040 as the best replacement strategy.

1041  
1042 In the Cost Benefit analysis, we have applied three scenarios: "Like and Kind",  
1043 "Current", and "Proposed". Like and Kind involves the replacement of pipes with  
1044 similar diameters and pressure, and may be considered as a reactive strategy.  
1045 As I stated above, PGL's current approach is an example of a maintenance-  
1046 based strategy. In my opinion, the continuance of a maintenance-based  
1047 approach could result in eventual failures that would necessitate a reactive  
1048 strategy that would preclude the application of better proactive strategies. As I  
1049 will demonstrate further in my testimony, a proactive approach that replaces  
1050 mains on an accelerated basis is best suited to serve PGL's future needs, and is  
1051 considered as the "Proposed" strategy in the analysis.

1052  
1053 **Q What technology options or alternatives were identified and evaluated?**

1054 **A** PGL is always looking for new efficient technologies. The model, however,  
1055 assumes that PGL continues using its existing technology, such as directional  
1056 drilling, dead insertion (installing new pipe in abandoned pipe) and double  
1057 decking in the current and proposed scenarios. Any benefits from future  
1058 alternative technology options which emerge will increase efficient operation and  
1059 possibly provide additional savings on top of the O&M cost reductions currently  
1060 estimated by the model.

1061

1062 **Q What are the benefits for each technology considered?**

1063 A The benefits of directional drilling include reduced surface restoration costs which  
1064 can represent up to 50% of installation costs compared to open trenching. Similar  
1065 savings are achieved by moling, auguring and dead insertion. However, the use  
1066 of double decking has the potential for reducing future O&M cost.

1067  
1068 By using these technologies PGL has focused not only on reducing current  
1069 construction costs, but on future O&M expenditures as well.

1070

1071 **Q What proposed technology approach was utilized for the cost analysis?**

1072 A The cost benefit analysis assumes PGL continues with its existing technology  
1073 approach, as described above.

1074

1075 **Q What approaches to pipe replacement did you consider?**

1076 A There are a number of approaches to pipe replacement selection: individual pipe  
1077 segments based on risk, pipe by type and age, individual blocks determined on  
1078 engineering grounds, and zone replacement. The replacement of individual pipe  
1079 segments based on either risk, or on type of pipe and age was considered.  
1080 Essentially in a maintenance-type strategy, these selection criteria are equivalent  
1081 to identifying and replacing individual pipe segments based on UMRI ratings, or  
1082 in the latter case, by the individual factors of pipe type and age which could  
1083 contribute to the UMRI ratings. An approach involving somewhat larger scale  
1084 would include the identification of individual blocks based on engineering criteria.  
1085 Zone replacement was considered to convert the low-pressure system to

1086 medium-pressure, while reducing the risk of CI/DI pipe and creating the best  
1087 economic efficiencies for construction costs. There are also certain operation and  
1088 maintenance economies of scale inherent in zonal replacement. For example, if  
1089 all pipes within a zone have been replaced with plastic, the less frequent leak  
1090 survey requirements of plastic pipe can be applied to labor-intensive leak survey  
1091 scheduling, all within a designated geographic area. Also, replacement of steel  
1092 pipes with plastic would result in the reduction of corrosion inspections that would  
1093 be needed.

1094  
1095 In the cost benefit analysis model, Scenario 3 assumes that replacement projects  
1096 will be based on both risk and zonal means. In my opinion this approach  
1097 ensures that high-risk segments will continue to be replaced, while potentially  
1098 gaining the efficiencies and benefits of larger zone replacements, such as  
1099 economic opportunities in material and labor negotiations.

1100

1101 **Q Why was the zone replacement approach chosen?**

1102 **A** Perhaps the most visually compelling reason for choosing a zone replacement  
1103 approach can be seen in the attached Exhibits SDM-1.20 (Low-pressure System  
1104 CI/DI Map) and SDM-1.21 (Medium-pressure System CI/DI Map). The  
1105 ubiquitous distribution of CI/DI pipe in PGL's system does not lend itself to  
1106 isolated replacement strategies that would ignore synergies of coordinated  
1107 removal within pre-planned zones.

1108

1109 Zonal replacement would allow PGL to move from the piecemeal approach of  
1110 removing individual pipes based on a maintenance history and cost reduction  
1111 basis, to a comprehensive basis that would maximize the opportunity of low-  
1112 pressure to medium-pressure conversion and removal of CI/DI pipes. Zonal  
1113 replacement would also potentially result in greater cost reductions per mile of  
1114 pipe replaced. CI/DI pipes within the existing medium-pressure system in the  
1115 replacement zone would also be replaced.

1116  
1117 I have not included the construction cost savings due to economies of scale  
1118 related to larger replacement zones and benefits accrued as a result of this  
1119 approach to contractor pricing and PGL efficiencies. It is my opinion that there  
1120 are additional savings opportunities related to providing contractors with a  
1121 guaranteed volume of continuous work around which they can plan their  
1122 resources and minimize overhead management cost. Further, there are  
1123 additional savings opportunities from the economies of scale for PGL meter  
1124 setting crews, in-the-field inspectors, and the use of value engineering. While  
1125 these savings cannot be quantified at this time, based on my experience, I would  
1126 expect such savings to occur.

1127 Zonal replacement would provide cost savings to the City of Chicago and  
1128 projects of other utilities by facilitating the coordinated movement of equipment,  
1129 traffic, and street restoration. Also, zonal replacement could potentially reduce  
1130 the cost associated with multiple independent projects.

1131 Another non-cost related benefit of zonal replacement is that it would allow for a  
1132 planned approach that minimizes unexpected third-party incidents, service  
1133 interruptions and traffic disruptions on an ongoing basis. This will be of particular  
1134 importance during the likely Chicago 2016 Olympic events, or other large  
1135 construction venues.

1136

1137 **Q What are the parts that would you expect to make up a main replacement**  
1138 **program?**

1139 A The zones suggested for replacement would be determined by the optimization  
1140 of three components: enforcement, condition, and plan. Enforcement  
1141 components would be determined by coordination with the City of Chicago, which  
1142 is already responsible for issuing permits for and scheduling utility and public  
1143 works projects. The condition of pipes, based on their UMRI score, would weigh  
1144 into the selection of candidate zones. Finally, zone boundaries and selection  
1145 would depend on technical and non-technical factors.

1146

1147 **Q What technical and non-technical factors need to be considered in**  
1148 **determining the quantity and timing of replacement zones?**

1149 A Under the accelerated replacement plan, we estimate that PGL could have  
1150 upwards of 12 zones being worked on per year. Each zone could be comprised  
1151 of a number of projects. The size and composition of mains, services and meters  
1152 within a given zone will depend on a number of factors:

- 1153 • UMRI segment scores;
- 1154 • Available pressure and capacity;

- 1155 • Type of streets;
- 1156 • Condition of mains and services;
- 1157 • Consequence of an adverse event; and
- 1158 • Other planned infrastructure projects by the City of Chicago.

1159

1160 Regardless of whether a zone approach or some other approach is implemented,  
1161 PGL may need to install additional infrastructure before the low-pressure areas  
1162 can be replaced.

1163

1164 **Q Please summarize the system modernization cost scenarios considered.**

1165 **A** Three main scenarios were considered in the cost benefit analysis:

- 1166 • Scenario 1 - Like and Kind Replacement
- 1167 • Scenario 2 - Current Replacement Program (Zinder Engineering, Inc. and  
1168 Kiefner and Associates, Inc.)
- 1169 • Scenario 3 - Proposed Replacement Program

1170

1171 In both Scenarios 1 and 2, we assume a 45-mile per year replacement program  
1172 of cast iron, ductile iron and steel pipe (in the low-pressure system) continuing  
1173 from 2011, which would lead to complete retirement by 2060 or a 49-year  
1174 replacement. However, in Scenario 2 we assume that the low-pressure system  
1175 is replaced by a medium-pressure system, and double decking is used for 70%  
1176 of the new 2" plastic pipe installed. As a result, more pipe is installed than  
1177 replaced in Scenario 2, and the estimated total capital cost for Scenario 2 is

1178 slightly more than Scenario 1 due to the cost of moving inside meters outside  
1179 and additional regulator stations and city gate stations.

1180  
1181 The proposed accelerated replacement program is modeled in Scenario 3,  
1182 assuming a 114-mile per year program that would lead to complete retirement by  
1183 2030. The replacement strategy and technology are the same for Scenarios 2  
1184 and 3 but the replacement period is 49 years in Scenario 2 versus 19 years in  
1185 Scenario 3. Cost savings (reductions) are obtained from the difference between  
1186 Scenario 2 and Scenario 3. Cost Savings per customer are based on PGL's total  
1187 customer count.

1188

1189 **Q How were the estimates of capital cost developed?**

1190 **A** The estimates of capital cost were developed using actual cost information  
1191 provided by PGL's Operations group. The contractor construction costs for  
1192 various activities, such as main pipe installation, plastic service pipe installation,  
1193 and meter installation on a per unit basis, were provided. Using the 30-year plan  
1194 being developed by PGL that outlines the amount, type and size of pipe to be  
1195 abandoned and new pipe to be installed, we projected the pipe installation cost  
1196 assuming that new main would be installed at a constant rate for each pipe size.  
1197 In Scenario 3, however, we included 5-year ramp up and 2-year ramp down  
1198 periods in construction to allow time for the additional labor required to be  
1199 trained.

1200

1201 All cost projections are in 2010 dollars and include adjustments for inflation using  
1202 90% of the labor and 10% of the material cost escalation rates projected for the  
1203 pipeline construction industry in the Chicago area. The capital costs are  
1204 segregated by the plant accounts used in the Rider ICR and the categories are  
1205 as follows:

- 1206 • Account 376, Distribution Mains
- 1207 • Account 380, Services
- 1208 • Account 381, Meters, including Meter Installations
- 1209 • Account 383, House Regulators
- 1210 • Account 378 & 379, Abandon Regulator Stations
- 1211 • Account 378 & 379, City Gate Stations
- 1212 • Account 378 & 379, New Regulator Stations

1213

1214 **Q What are the most significant cost drivers?**

1215 **A** The most significant cost drivers for capital are the main and service installation  
1216 costs and the meter replacement costs. Most of the savings in overall capital  
1217 costs are a result of the shorter replacement time period due to the time value of  
1218 money.

1219

1220 For O&M, the significant savings drivers are related to the savings from leak  
1221 repairs, lost gas, and inside safety inspections. These savings are a result of the  
1222 expected lower leak rate on the new main system and reduced cost in inspecting  
1223 outside meters versus inside meters. These figures have been provided in Exhibit  
1224 SDM - 1.16 and SDM – 1.17

1225 The capital cost and O&M savings are also sensitive to labor, material and  
1226 inflation escalation factors. As we have seen in recent years, construction costs  
1227 and materials have seen unprecedented escalation due to demand for  
1228 domestically produced energy.

1229

1230 **Q If the zone approach is used, will low risk pipe be replaced before high risk**  
1231 **pipe?**

1232 A Under a zone replacement approach the higher-risk infrastructure will continue to  
1233 be replaced for reasons of condition (e.g., main segments exceeding a UMRI  
1234 threshold score of 6) or enforcement (e.g., sewer improvement). The risk  
1235 associated with mains and services is one consideration in establishing and  
1236 prioritizing a zone project, but not the only factor. The prioritization of zones  
1237 considers replacement impact on customers and businesses, availability of  
1238 capacity and pressure, higher-risk infrastructure and program costs.

1239

1240 **Q Why is it necessary to put some medium-pressure infrastructure in place**  
1241 **prior to replacing cast iron and ductile iron pipe?**

1242 A In order to increase the operating pressure using pipe of smaller diameter, there  
1243 must be adequate capacity and pressure in the mains feeding the segment or  
1244 zone. When either adequate capacity or pressure is not available, additional  
1245 incremental investments must be made in advance of infrastructure  
1246 improvements. Although it is possible to replace the existing pipe with the same  
1247 size pipe and up-rate or increase the pressure at a later date, this increases the

1248 program cost. These incremental investments may include new city gate  
1249 stations, new or redesigned high-pressure to medium-pressure regulator stations  
1250 or additional medium-pressure pipe.

1251

1252 **Q Why does the Accelerated Infrastructure Replacement Program show more**  
1253 **pipes being installed than pipe replaced?**

1254 A One previously described technique that will be employed in replacing existing  
1255 higher-risk pipe is double decking. Double decking has several benefits:

- 1256 • Removes the main from the congestion of utilities already under the street;
- 1257 • Reduces future maintenance costs;
- 1258 • Reduces the potential of excavation damage to gas facilities;
- 1259 • Reduces the average length of service lines;
- 1260 • Reduces the number of long side services (i.e., services running from one  
1261 side of the street where the main is installed to the opposite side of the street  
1262 where the building being served is located); and
- 1263 • Reduces program installation costs.

1264

1265 **Q How were O&M costs and savings incorporated into the cost analysis?**

1266 A The operating costs and savings included in the analysis were:

- 1267 • Reduced leak survey expense;
- 1268 • Reduced leak repairs;
- 1269 • Reduced regulator inspection and maintenance expense;
- 1270 • Reduced lost gas; and

1271 • Reduced number of emergency responses.

1272

1273 Records of reported operation and maintenance work units and costs were  
1274 reviewed. Using this information for PGL's current replacement program  
1275 (Scenario 2) and the accelerated replacement program (Scenario 3), the  
1276 operation and maintenance expenses for the remaining pipe (including related  
1277 facilities such as regulator stations) to be replaced/abandoned and the new pipe  
1278 (including related facilities such as valves and regulator stations) to be installed  
1279 were estimated. These operation and maintenance costs were estimated for the  
1280 period from 2011 to 2060. The savings is the difference between the Scenario 2  
1281 and Scenario 3 costs in 2010 dollars.

1282

1283 **Q What are the non-O&M benefits associated with the Accelerated**  
1284 **Infrastructure Replacement Program?**

1285 **A** There are a number of additional qualitative benefits associated with an  
1286 Accelerated Infrastructure Replacement Program that are not associated with  
1287 operations and maintenance, which have been described throughout my  
1288 testimony:

- 1289 • Greater appliance choice by customers;
- 1290 • Reduced greenhouse gas emissions;
- 1291 • Increased availability of higher-efficiency appliances;
- 1292 • Reduced cost of gas utilization equipment;
- 1293 • Improved customer safety;

- 1294           • Fewer inside safety inspections which inconvenience customers by requiring  
1295           them to be at home;  
1296           • Outside access to service shut-off valves at meter sets; and  
1297           • Greater application of service line excess flow valves.

1298

1299           As an integral part of a conversion from low-pressure to medium-pressure, PGL  
1300           would relocate meters from inside to the outside of buildings. Currently,  
1301           according to PGL, there are 540,678 inside meters in PGL's distribution system.  
1302           Moving meters to the outside of buildings would facilitate maintenance of  
1303           automated meter reading equipment, would reduce bad debt (unpaid gas bills)  
1304           and its corresponding share of burden on all customers, and most importantly,  
1305           would enhance safety by providing outside access to service shut-off valves at  
1306           meter sets.

1307

1308           An additional safety benefit would be the installation of temperature-  
1309           compensated meters and excess flow valves that operate at pressure ranges  
1310           within the medium-pressure system, but above those available in the current low-  
1311           pressure system.

1312

1313   **VI.   Implementation of the Accelerated**  
1314   **Infrastructure Replacement Program**

1315   **Q**   In your opinion is PGL capable of efficiently and effectively managing the  
1316           Accelerated Infrastructure Replacement Program?

1317   **A**   Yes.

1318

1319 **Q Please describe what is entailed in Program Management.**

1320 A Program Management is the disciplined, systematic orchestration of manpower,  
1321 time, dollars, materials, equipment and information to plan, design, construct and  
1322 deliver large, complex capital investment programs. From our experience,  
1323 effectively executing an accelerated infrastructure program requires identifying  
1324 what systems, processes, skills and resources are necessary to "ramp up" to the  
1325 expected level necessary to meet the program's commitments. Therefore, pre-  
1326 planning and the identification of any gaps that may hinder executing the  
1327 program effectively and efficiently are needed to insure the proper costs and  
1328 needs are understood in the implementation plan.

1329

1330 **Q Please describe what is entailed in Quality Assurance.**

1331 A Quality Assurance (QA) ensures that PGL plans its work to achieve a quality  
1332 product and that its work is carried out in a manner that produces the expected  
1333 quality. This includes assuring that whatever procedures are established for the  
1334 planning, design, and construction phases to meet requirements established by  
1335 PGL, the Commission, the Occupational Safety and Health Administration, the  
1336 City of Chicago or any other authority having jurisdiction are followed and  
1337 documented.

1338

1339 **Q How will PGL monitor the costs of and savings from the accelerated**  
1340 **program?**

1341 A Ms. Grace (PGL Ex. VG-1.0) describes Rider ICR and the proposed reporting  
1342 and audit provisions of that rider.

1343

1344 **Q What program and management processes will be needed to efficiently and**  
1345 **effectively implement the Accelerated Infrastructure Replacement**  
1346 **Program?**

1347 A One of the lessons learned in the cast iron replacement program in the City of  
1348 London, UK, was the need to create a dedicated team to manage the zonal  
1349 replacement program. We would expect that PGL's program implementation plan  
1350 would address the following at minimum:

- 1351 • Organizational Structure;
- 1352 • Staffing Levels and Skills Assessment;
- 1353 • Adequacy of Business Process and Systems;
- 1354 • Roles and Responsibilities of PGL Staff and Service Providers;
- 1355 • Program Budget;
- 1356 • Cost Estimating;
- 1357 • Buildability/Constructability/ Maintainability Review;
- 1358 • Program Schedule;
- 1359 • Cost Management, Control and Reporting;
- 1360 • Contract Administration;
- 1361 • Project Records, Document and Drawing Controls;

1362 • Quality Control/Assurance; and

1363 • Performance Measurement.

1364

1365 **Q How will PGL address the efficiency of its management programs?**

1366 A To date PGL has been managing its current main replacement program through  
1367 business processes that include planning, scheduling and monitoring  
1368 replacement projects. However, the proposed accelerated replacement program  
1369 will require the current replacement rate to more than double. From my  
1370 experience, when a company significantly increases its capital budget, a gap  
1371 review of existing tools, processes, practices and resources must be undertaken.  
1372 Such reviews often result in changes that are necessary to improve program  
1373 management and execution. These improvements are developed and phased in  
1374 during a program ramp up period.

1375

1376 PGL recognizes the need to review its replacement program management  
1377 process as part of the pre-planning effort.

1378

1379 **Q Are there any barriers to efficiently and effectively implementing the**  
1380 **Accelerated Infrastructure Replacement Program?**

1381 A Yes. PGL is expected to hire additional union personnel to perform meter  
1382 installation and relights. To efficiently implement the accelerated program it may  
1383 seek to change some work rules. Additional personnel, equipment and vehicles

1384 will be necessary. Limited space at existing operating shops may need to be  
1385 addressed.

1386  
1387 Although stakeholder communication and coordination will be a challenge, we do  
1388 not see it being a barrier.

1389  
1390 **Q How will the issue of resourcing qualified and skilled people be addressed?**

1391 A This program will involve a need to hire both union and management company  
1392 personnel and outside contractors. This was considered in selecting the  
1393 replacement period. To effectively address the resourcing issues, we would  
1394 expect that a program resource and skills assessment and staffing plan be  
1395 developed prior to 2011. The accelerated replacement program will need to be  
1396 ramped up. In our cost benefit analysis we have included a five-year ramp up  
1397 period and two-year ramp down period. As stated previously in this testimony,  
1398 incremental investment will be necessary. A portion of the incremental  
1399 investment will take place during the initial two years, which should enable the  
1400 transition to the peak main replacement level. PGL has recognized the need to  
1401 address this issue.

1402  
1403 **Q Will additional training and professional development be required in order  
1404 to ramp up the program?**

1405 A While a significant portion of the program will be outsourced to contractors,  
1406 additional internal training and professional development will be necessary for  
1407 PGL staff, including engineers, project managers, and inspectors. To manage

1408 this additional training and professional development, the program is expected to  
1409 be ramped up over five years. These incremental costs for training and  
1410 professional development are included as IOM in the cost benefit analysis.

1411  
1412 Contractor personnel will receive skills training in compliance with existing  
1413 operator qualification program.

1414

1415 **Q How might restoration costs be controlled?**

1416 **A** In my experience with the industry, excavation and restoration costs can account  
1417 for up to 75% of maintenance expenditures. PGL reports that street restoration  
1418 costs have more than tripled in the last five years. In 2008, PGL spent  
1419 \$7,284,133 on restoration costs related to installing 86.5 miles of main. This cost  
1420 stems from a variety of factors including more stringent requirements of the City  
1421 of Chicago and the Chicago Department of Transportation, spoil disposal, labor,  
1422 and street restoration materials. In nearly all cases, removed spoil is not eligible  
1423 for use as fill and must be transported and disposed of in a landfill. The City of  
1424 Chicago is stringent in its resurfacing requirements in an effort to assure that all  
1425 entities leave the city streets in a high quality and lasting condition.

1426 As stated earlier, one of the advantages of an accelerated infrastructure  
1427 replacement program, if it incorporates a zonal work plan, is the congregation of  
1428 work forces and the advantageous use of economies of scale in the employment  
1429 and coordination of excavation and restoration workforce, equipment and  
1430 transportation. For example, spoil material is currently sent to landfills after

1431 collection at PGL's facilities and testing. As a result, PGL's shops must now  
1432 secure permits to operate as transfer stations. An accelerated program with  
1433 zonal strategy would create large enough loads in near proximity to facilitate the  
1434 cost-effective use of contractors who would haul, test, and take materials to  
1435 landfills without use of PGL's shops.

1436  
1437 In addition, coordination with the City of Chicago would reduce the likelihood that  
1438 a particular site would undergo repeated restoration for multiple projects by the  
1439 City and other utilities, resulting in restoration cost controls to both PGL and the  
1440 City's public works projects.

1441  
1442 **Q Are there any additional technologies that can be utilized to significantly**  
1443 **reduce restoration costs and public inconvenience and improve public and**  
1444 **employee safety?**

1445 **A** Yes, in my experience the use of "small hole" technologies is one potential  
1446 technology that has been proven to significantly reduce restoration costs and  
1447 public inconvenience, and improve public and employee safety. Other utilities  
1448 that have implemented these technologies experienced savings as great as 50%  
1449 in the performance of routine work associated with maintaining a gas distribution  
1450 network. The savings primarily result from a reduction in excavation and  
1451 restoration costs associated with openings to conduct repair and capital  
1452 activities. It is my opinion that PGL may be able to use this technology to reduce  
1453 its restoration costs and improve productivity. See Exhibit SDM - 1.22 for detail.

1454

1455 **Q Because these technologies provide so many benefits, why are they not**  
1456 **included in your cost analysis?**

1457 A I did not include small hole technology in the cost analysis because although the  
1458 technology has been proven for use in other cities with similar conditions, the  
1459 City of Chicago's construction code, like that of several other cities, has not been  
1460 updated to accommodate the technology. Small hole technology involves  
1461 techniques that are not applicable to the proscribed specifications in the current  
1462 code. For example, one of the cost advantages of small hole technology is in the  
1463 use of vacuum excavation units which collect the minimal amount of spoil from  
1464 excavation and later replace the material as fill. This can be accomplished by  
1465 sifting the spoil material to remove unacceptable debris. However, the City of  
1466 Chicago at this time does not allow self-sifting of spoil to meet its fill  
1467 requirements. Another example is in the requiring of additional cut back and  
1468 resurfacing, which is illustrated in the City of Chicago's construction code for  
1469 more conventional trenching and excavation, but not for the extraction of small  
1470 holes which require much less filling and restoration.

1471  
1472 Obtaining City of Chicago approval and implementing vacuum  
1473 excavation/keyhole and coring technologies would help PGL reduce  
1474 expenditures on repair and replacement activities, improve quality of street  
1475 restoration, and provide several other benefits in reduced traffic disruption. In  
1476 addition, this technology would minimize environmental impact and improve  
1477 public and worker safety.

1478

1479 **VII. Compliance and Transparency**

1480 **Q How will the Commission be able to monitor PGL's accelerated**  
1481 **replacement program, the recovery of costs for this program and the flow**  
1482 **of reduced system cost back to the customers?**

1483 **A** PGL's intent and goal is to provide transparency of this program for the  
1484 Commission. The goal is to provide the people of the City of Chicago the  
1485 modern infrastructure and improved safety they deserve, as well as to flow the  
1486 reduced system costs back to them when those benefits are achieved.

1487

1488 If approval for Rider ICR is granted, allowing the accelerated main replacement  
1489 program to proceed, PGL will commit to providing Commission Staff annually with  
1490 a detailed report showing the progress and plans for its accelerated replacement  
1491 program. The flow of reduced system operations and maintenance costs to  
1492 customers, when achieved, will be apparent in the annual reconciliation process.

1493

1494 **VIII. Conclusions**

1495 **Q In summary, in your opinion, does the cost-benefit analysis, technologies**  
1496 **to be applied by PGL, functionalities of the proposed system and other**  
1497 **items addressed in your testimony support PGL's Accelerated**  
1498 **Infrastructure Replacement Program and its requested Rider ICR?**

1499 **A** Yes. In my opinion, the cost analysis clearly demonstrates that accelerating the  
1500 replacement program will significantly reduce the customer's total cost of

1501 modernizing the gas distribution system. Rider ICR enables customers to almost  
1502 immediately realize the benefits of reduced operating and maintenance costs.  
1503 Most importantly the customers benefit from a safer and more reliable medium-  
1504 pressure gas distribution system, which will allow customers to purchase the  
1505 latest and most fuel efficient, environmentally friendly gas utilization equipment.

1506

1507 **Q Does this conclude your testimony?**

1508 **A Yes**

1509
